# Mission impossible: Disproving failed conjectures

Bachelor Thesis

Author: Heba Aamer Anwar Mohamed  
Supervisor: Professor Dr. Stephan Schulz  
Submission Date: XX July, 2015

This is to certify that:

- (i) the thesis comprises only my original work toward the Bachelor Degree
- (ii) due acknowledgement has been made in the text to all other material used

---

Heba Aamer Anwar Mohamed  
XX July, 2015

# Acknowledgments

First, I have to thank my supervisor Professor Dr. Stephan Schulz for his continuous support and understanding.

Second, I have to thank my whole family for their support and encouraging to achieve this stage of my education.

Third, Many thanks should be said to my friends the ones who travelled with me and the others who were in Egypt for their help, encouraging.

# Abstract

In the past few decades the field of automated theorem proving (ATP) has been flourishing and improving a lot by the enormous amount of research devoted to it. That interest came from its importance as well as its various uses in different fields such as mathematical reasoning.

ATP comes along with another process which is model generation/computation/construction from a certain (counter) satisfiable specification/problem. Model generation has usages that ATP alone won't have the effect that it has with it, and that could be noticed in Software/Hardware verification, debugging various systems.

Here in this project we added a model generation technique for a subclass in First Order Logic named Effectively Propositional Calculus in an existing theorem prover "E" where we transform the axioms of the specification into a certain form called range restricted form, and then after reaching saturation, we apply Bachmair and Ganzinger model construction technique to get the model.

# Chapter 1

## Introduction

Introduction

# Chapter 2

## Background

This chapter is concerned with introducing and familiarizing the reader to the theoretical concepts behind this project, and give the reader a background on the theorem prover E as well.

### 2.1 Background on first order logic topics

FOL, which is also known as first order predicate logic, is an expressive logic that allows us to formulate most of our spoken language sentences in a defined way such that it could be further handled with rules such as simplification, inference rules, etc.

We could represent formulas in FOL in so many forms. So 2.1.1 will be devoted to that part of background.

Moreover, in general the universe of FOL is infinite because of the existence of the quantifiers and function terms. So in 2.1.2 some topics related to that property will be mentioned including Herbrand Universe.

Also this project is concerned to a specific class of FOL its calculus named EPR, and this will be discussed in 2.1.4.

#### 2.1.1 Different forms of FOL

FOL can be represented in different forms. Even some algorithms need to work with specific one. Moreover, there are some procedures that could transform a formula from one form to another. Here in this part, we will discuss the most important forms and the relevant ones to the project.

- 1- general form
- 2- clausal normal form
- 3- prenex normal form
- 4- skolem normal form

**General Form**

General form

**Clausal normal form**

Clausal normal form (CNF)

**Prenex normal form**

Prenex normal form (PNF)

**Skolem normal form**

Skolem normal form (SNF)

**2.1.2 The universe of FOL**

Discuss the infinity of the universe in general.  
And then mention the Herbrand Universe.

**2.1.3 Skolemization**

Skolemization is the step that transforms PNF formulas into SNF. In which all the existentially quantified variables are removed and replaced by some function terms and its arguments are all the universally quantified variables appeared before the one in concern. Example for a formula in PNF:

$$\exists W \forall X \forall Y \exists Z (P(a, W, X, Y, Z)).$$

After it transformed into SNF:

$$\forall X \forall Y (P(a, b, X, Y, f(X, Y))).$$

### 2.1.4 EPR

EPR or sometimes known as Bernays-Schoenfinkel class is a class of first order logic in which all of its formulas follow the following format:

$\exists^* \forall^* F$ , where  $F$  is the formula. Moreover,  $F$  has no proper functions symbols (all functions present are nullary ones "constants").

Example for a formula in EPR:

$$\exists X \exists Y \forall Z (P(a, X, Y, Z)).$$

Keeping 2.1.3 in mind, this will make every skolemized formula that originally was in EPR format have no proper function symbols. After transforming the above equation, it will be:

$$\forall Z (P(a, b, c, Z)).$$

## 2.2 TPTP Problem set

TPTP problems are first order problems that are considered benchmarks to measure the performance of the theorem provers. TPTP problem set consists of different categories of problems such as : PUZ, NLP, etc....

## 2.3 The theorem prover E

E is a saturation-based theorem prover that is concerned with full FOL with equality. It is known to be a fast one because of the unique and various heuristics implemented in it. The current state of E, that it could prove the un-satisfiability of set of axioms with the negation of the conjecture(s) by finding the empty clause, or returning the saturated set if the empty clause was not found and no more new clauses can be inferenced/simplified.

### 2.3.1 The main proof procedure

This part is devoted from giving a brief on the main proof saturation procedure.

Search state:  $U \ P$

$U$  contains unprocessed clauses,  $P$  contains processed clauses.

Initially, all clauses are in  $U$ ,  $P$  is empty.

The given clause is denoted by  $g$ .

while  $U \neq \emptyset$

$g = \text{delete best}(U)$

```

g = simplify(g, P )
if g ==
SUCCESS, Proof found
if g is not subsumed by any clause in P (or otherwise redundant w.r.t. P )
P = P - c  P - c subsumed by (or otherwise redundant w.r.t.) g
T = c  P - c can be simplified with g
P = (P - T ) - g
T = T - generate(g, P )
foreach c  T
c = cheap simplify(c, P )
if c is not trivial
U = U - c
SUCCESS, original U is satisfiable

```

Remarks: delete best( $U$ ) finds and extracts the clause with the best heuristic evaluation (see 3.3) from  $U$ . generate( $g, P$ ) performs all generating inferences using  $g$  as one premise, and clauses from  $P$  as additional premises. It uses inference rules (SP) or (SSP), (SN) or (SSN), (ER) and (EF). simplify( $c, S$ ) applies all simplification inferences in which the main (simplified) premise is  $c$  and all the other premises are clauses from  $S$ . This typically includes full rewriting, (CD) and (CLC). cheap simplify( $c, S$ ) works similarly, but only applies inference rules with a particularly low cost implementation, usually including rewriting with orientable units, but not (CLC). The exact set of contraction rules used is configurable in either case.

Fig. 2. Saturation procedure of E

### 2.3.2 Latest results

The latest results showed performance approaching 70% over all the CNF and FOF problems and this is according to [3]

# Chapter 3

## Methodology and Implementation

Methodology and Implementation

### 3.1 Transformations

The methods applied in the project to extract the models follows the transformations discussed in [1]. A brief on the transformations will be given in 3.1.1. Moreover, as mentioned before that this project is concerned with a sub-class of FOL which is EPR some simplifications to the transformations were made. Those simplifications will be discussed in 3.1.2.

#### 3.1.1 Original transformations

The original procedures discussed in [1] generally work for all sub-classes of FOL. Those procedures should be applied to a given set of axioms in a specific form "implication form" which is explained here – , and here – to know how to transform to that form.

Transformations are series of procedures, mainly about changing the clauses to certain form named range restricted form. In general the transformations deal with clauses in the implication form. Range restricted clauses: are the clauses in which all the variables that appear in the succedent must exist in the antecedent as well. Transformations also add a domain predicate that will help in finding the interpretations.

There are 3 types of transformations:

First 2 transformations: "Range restricting transformations" 'crr' and a variant of it 'rr' mainly responsible for changing the clauses to the range restricted form. The difference is that 'rr' adds elements to the domain when it needs them, while 'crr' enumerate the Herbrand Universe.

Second 2 transformations: "Shifting transformations" 'bs' and 'pf' mainly for preventing non-termination and generating unpleasant clauses from steps in 'rr'

Last transformation: "Blocking transformation" 'bl' mainly for detecting periodicity, so it defines a new predicate  $sub/2$  that represents a subterm relation

Order of applying those transformations is shifting -> range restricting -> blocking

### 3.1.2 Simplified transformations

This part is concerned about discussing the simplifications that were added to the original transformations highlighted in 3.1.1.

Keeping in mind the definition of EPR as mentioned here in 2.1.4.

So the following were made to each of the procedures:

- 1- Every step that only deals with proper function symbols is removed since they are not existing in EPR.
- 2- Any step or procedure that was introduced because of the existence of problems because of proper function symbols were removed as well. Ex.: pf, sh, and bl.

Therefore the resultant simplified procedures are the following:

For crr:

- (0) Initialization. Initially, let  $crr(M) := M$ .
- (1) Add a constant. Let  $dom$  be a fresh unary predicate symbol not in  $P$ , and let  $c$  be some constant. Extend  $crr(M)$  by the clause  $dom(c)$ . (The constant  $c$  can be fresh or belong to  $f$ .)
- (2) Range-restriction. For each clause  $H \rightarrow B$  in  $crr(M)$ , let  $x_1, \dots, x_k$  be the set of variables occurring in  $H$  but not in  $B$ . Replace  $H \rightarrow B$  by the clause  $H \rightarrow B \wedge dom(x_1) \wedge \dots \wedge dom(x_k)$ .

For rr:

- (0) Initialization. Initially, let  $rr(M) := M$ .
- (1) Add a constant. Same as Step (1) in the definition of crr.
- (2) Domain elements from clause bodies. For each clause  $H \rightarrow B$  in  $M$  and each atom  $P(t_1, \dots, t_n)$  from  $B$ , let  $P(s_1, \dots, s_n)$  be the term abstraction of  $P(t_1, \dots, t_n)$  and let  $\theta$  be the corresponding abstraction substitution. Extend  $rr(M)$  by the set  $dom(x_i) \wedge P(s_1, \dots, s_n) \rightarrow 1 \leq i \leq n$  and  $x_i \theta$ .
- (3) Range-restriction. Same as Step (2) in the definition of crr.
- (4) Domain elements from  $P$ . For each  $n$ -ary  $P$  in  $p$ , extend  $rr(M)$  by the set  $dom(x_i) \wedge P(x_1, \dots, x_n) \rightarrow 1 \leq i \leq n$ .

## 3.2 Code Flow

# Chapter 4

## Testing and Validation

Testing and Validation

### 4.1 Efficiency

#### 4.1.1 Memory Efficiency

The first part of the implementation which is related to applying the transformations to the the clause set introduces no memory leaks to the whole program.

Tools to check this:

1- Script implemented in E for giving a summary on the allocated and de-allocated memory structures, and the results showed that they are equal.

Ex.:

```
# -----  
# Total SizeMalloc(ed) memory: 68536168 Bytes (131507 requests)  
# Total SizeFree(ed) memory: 68536168 Bytes (131507 requests)  
# New requests: 214 ( 197 by SecureMalloc(), 17 by SecureRealloc())  
# Total SecureMalloc(ed) memory: 277647 Bytes  
# Returned: 214 ( 214 by FREE(), 0 by SecureRealloc())  
# SecureRealloc(ptr): 19 ( 17 Allocs, 0 Frees, 2 Reallocs)  
# -----
```

2- Tool named 'valgrind' which also showed the same results as the above script.

### 4.2 Accuracy of the transformations

The results of ./edisprover part is the same as the author of the paper implemented program in all the tested problems.
